Experiment 3

Student Name: Devjot Singh

UID: 23BCS10864

Branch: BE-CSE

Section/Group: KRG 2-A

Semester: 6th

Date of Performance: 28/01/2026

Subject Name: System Design

Subject Code: 23CSH-314

1. Aim: To design a social media platform similar to Facebook or Instagram

2. Objective:

- To understand social media application workflow.
- To design functional and non-functional requirements.
- To create system architecture (HLD).
- To design modules/classes (LLD).
- To implement core APIs for user authentication, posts, feed, likes, and comments.

3. Tools Used:

- Python – Backend logic implementation and URL generation algorithms.
- Flask – Lightweight web framework for developing RESTful APIs.
- Draw.io – Designing system architecture diagrams (HLD & LLD).

4. System Requirements:

A. Functional Requirements

- Client should be able to register and login to the application.
- Client should be able to create posts (text / image / videos).
- Client should be able to follow each other (or send friend requests).
- Client should be able to like or comment on posts.
- Client should be able to view feed of posts from users they follow.

B. Non-Functional Requirements

- Scalability

The system should support up to 500 Million Daily Active Users (500M DAU).

- Availability and Consistency

Since this is a social media application, Availability is prioritized over Consistency.

Reason:

If the application is not operational when required, there is no purpose in developing it. Minor delays in content propagation are acceptable compared to complete downtime.

Example: If Instagram is down for 1 hour, it is a major issue.

However, if a post takes 500 ms to reach followers while the system remains available, it is acceptable. Hence:

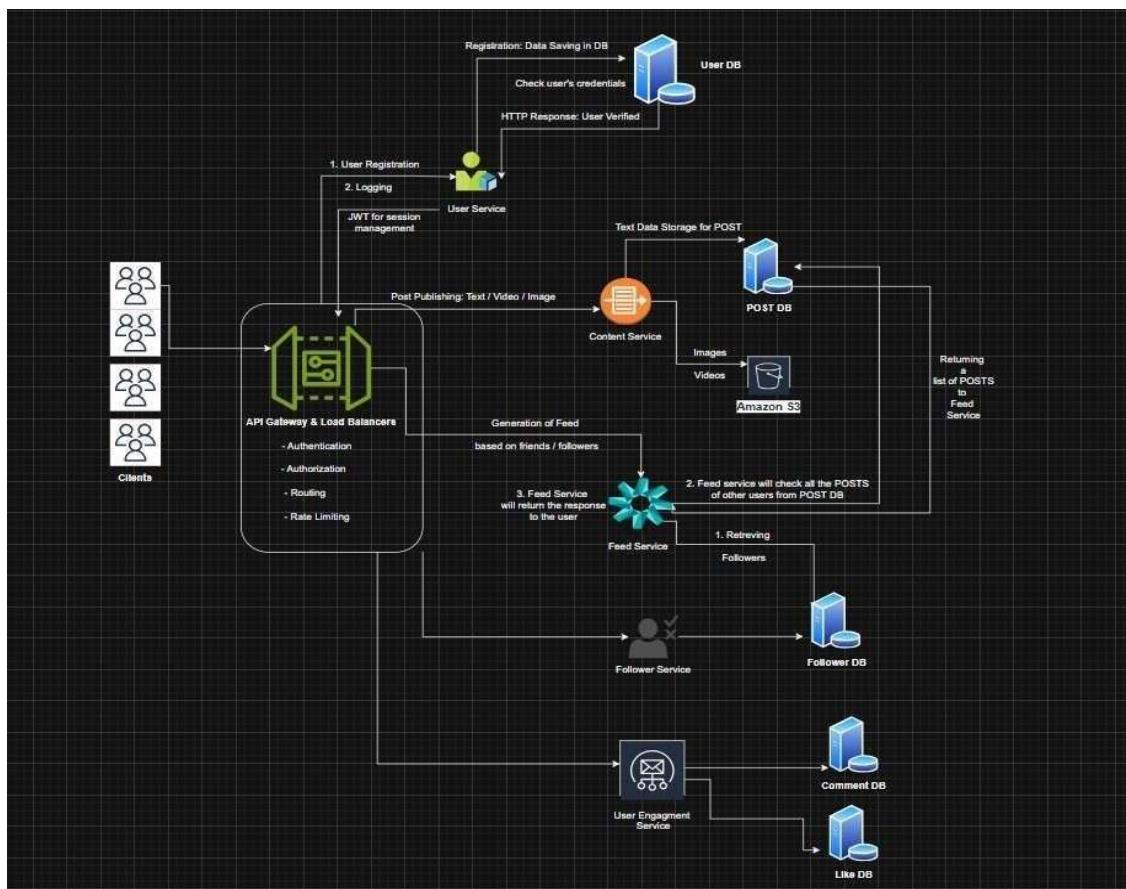

Availability >>> Consistency

- Latency

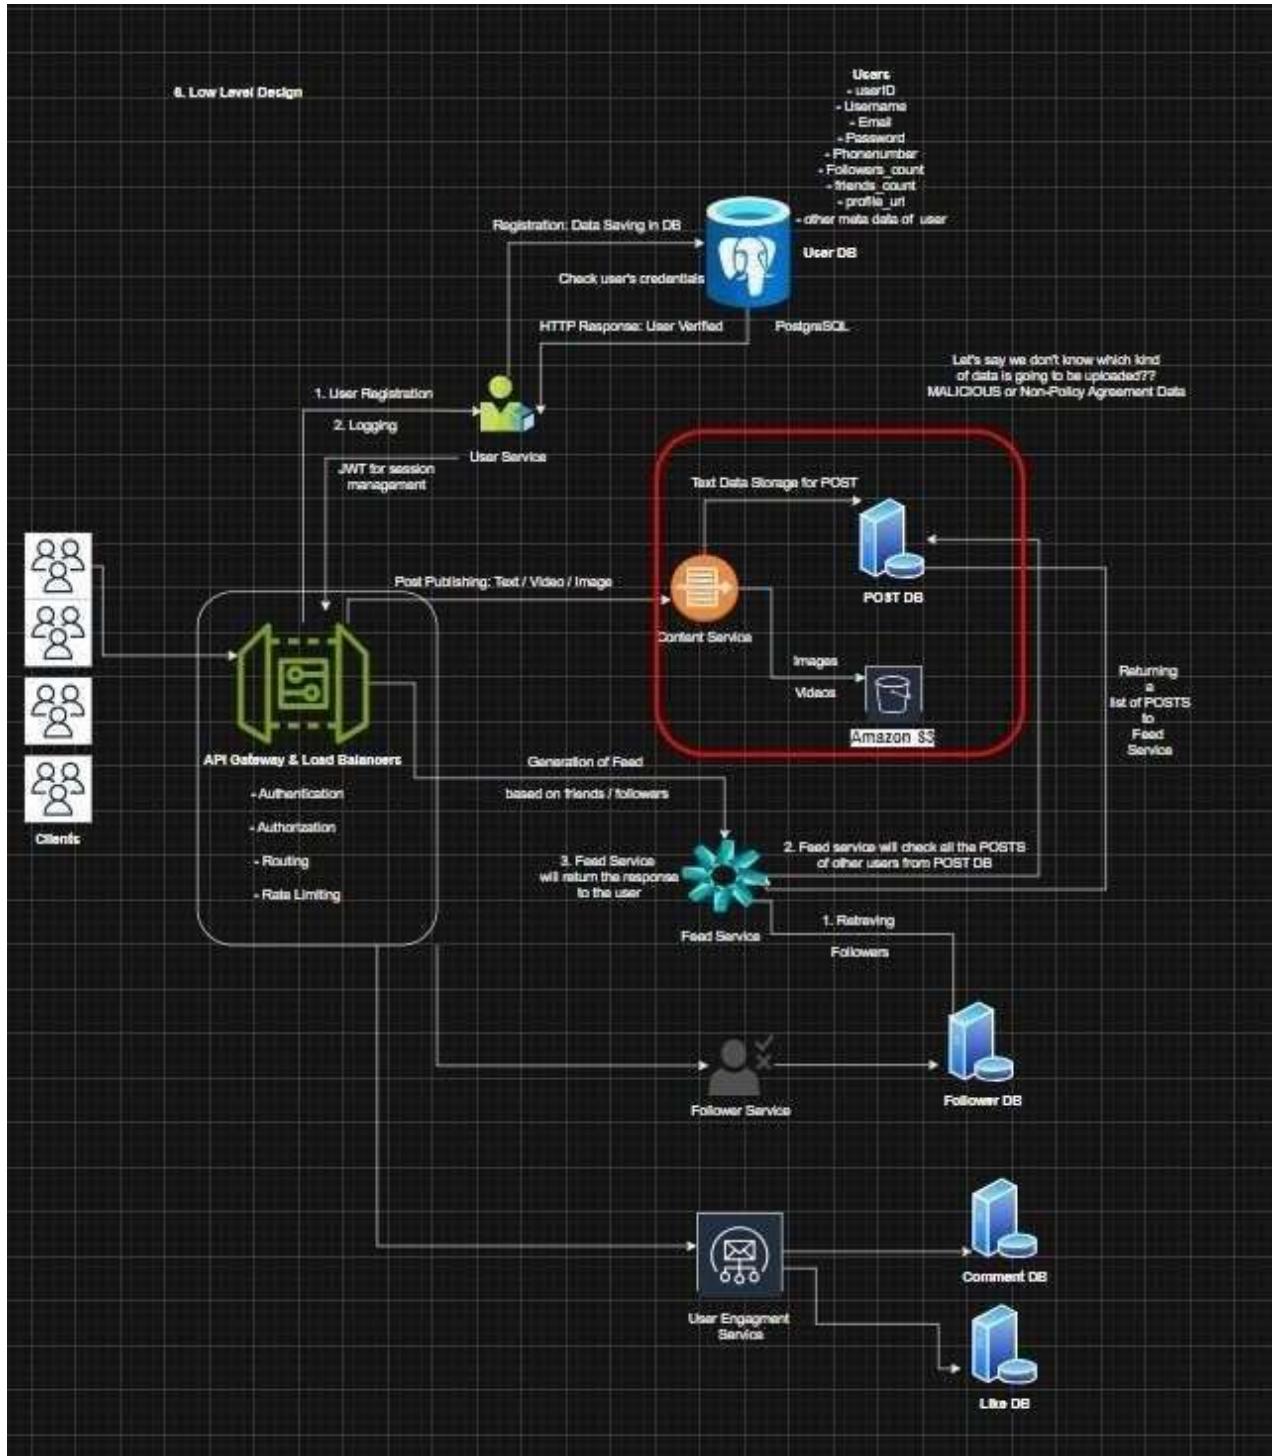

Uploading or publishing a post should take approximately 500 milliseconds to ensure a smooth user experience.

5. High Level Design (HLD):

The system follows a MICRO-SERVICE ARCHITECTURE / DISTRIBUTED:

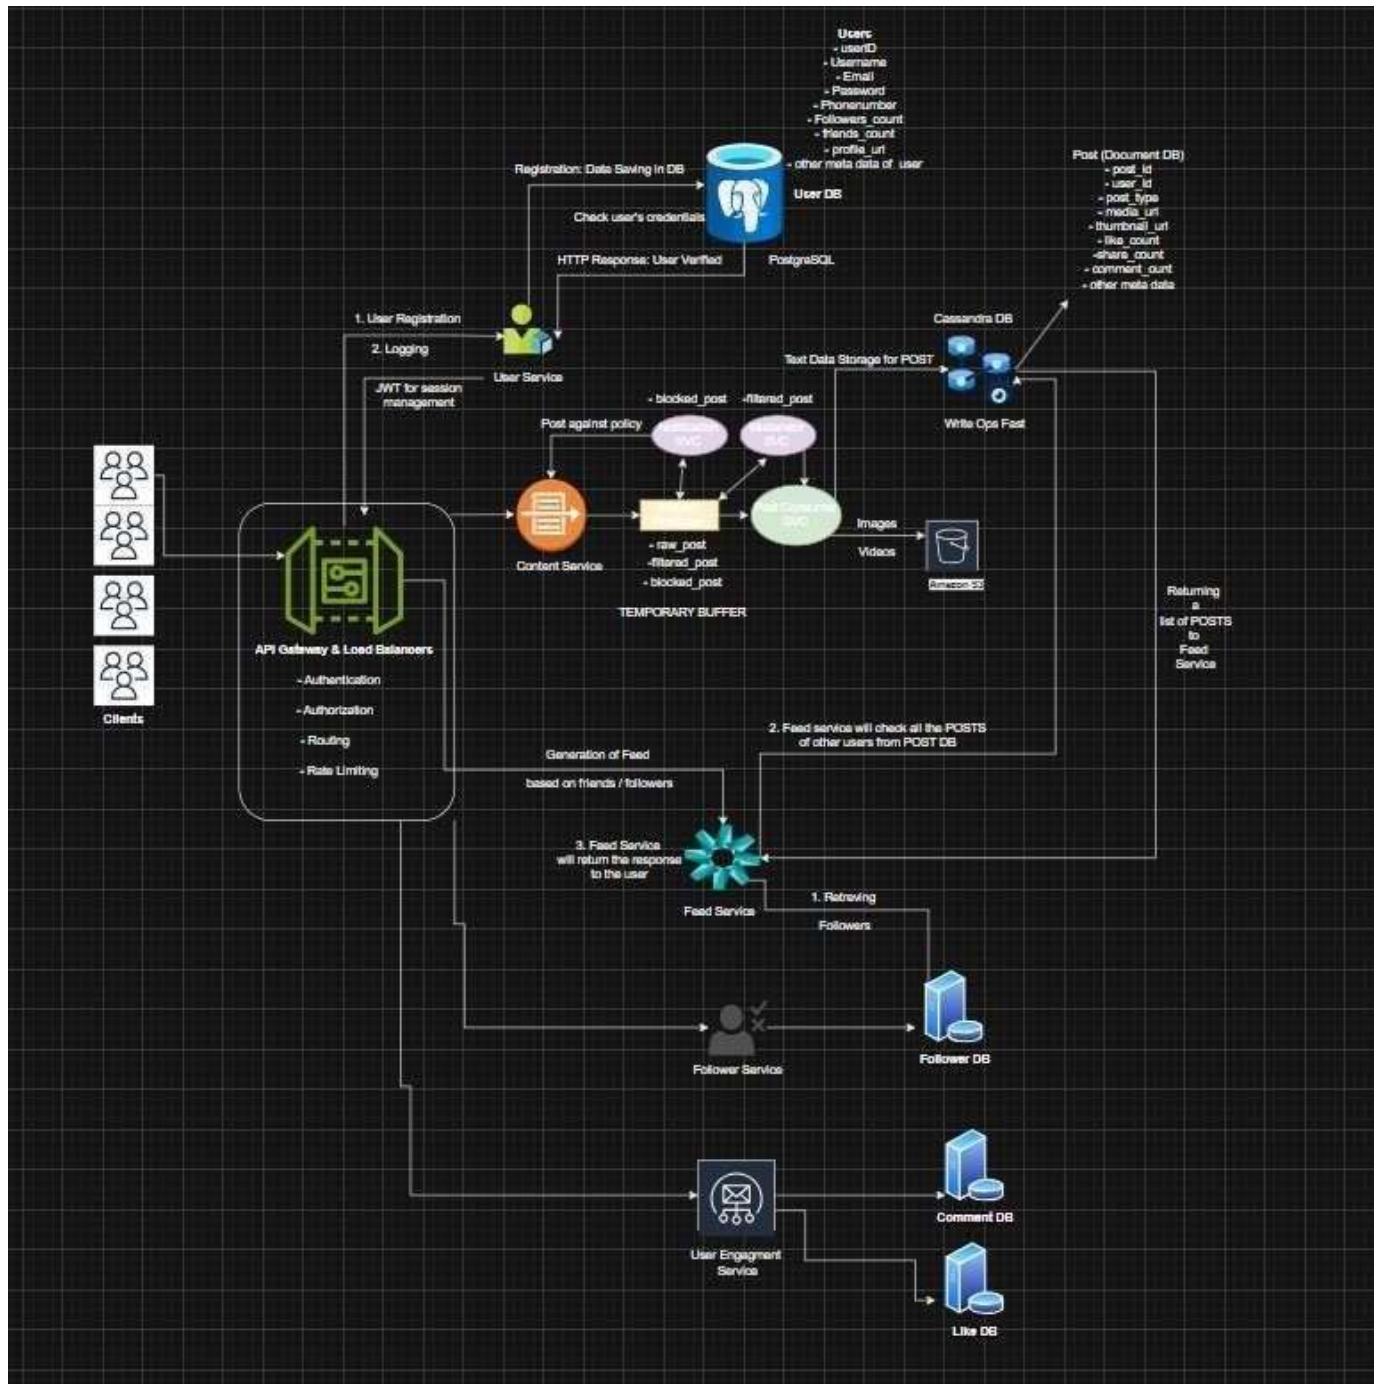

6. Low Level Design (LLD):

6. Scalability Solution

- Use horizontal scaling by adding multiple application servers behind a load balancer.
- Implement database sharding to distribute user and post data across multiple databases.
- Use caching (Redis/Memcached) to reduce database load for frequently accessed data like feeds and profiles.
- Store media files (images/videos) using CDN and cloud storage to improve performance and reduce server load.
- Apply asynchronous processing and message queues (Kafka/RabbitMQ) for tasks like notifications and feed updates.

7. Learning Outcomes (What I Have Learnt)

- Understood the workflow of a social media application system.
- Learned to design functional and non-functional requirements.
- Gained knowledge of high-level and low-level system architecture.
- Learned how scalability and availability are achieved in large-scale systems.
- Developed understanding of core APIs for user management, posts, and feed handling.
